Secure E-Health Framework Using Artificial Intelligence and Blockchain Technology (SEHFUAIBC)

JES Journal of Electrical Systems

Abstract: - There are a number of new technologies emerging in the healthcare sector that involve blockchain and artificial intelligence (AI). Data on healthcare indices are collected from the documents published on Web of Sciences and other Google surveys conducted by different governing bodies in order to collect information. The purpose of this review is to examine a wide range of aspects of blockchain and artificial intelligence, as well as how these two technologies can be integrated for the purpose of making a significant difference in healthcare by encouraging the implementation of generalizable analytical technologies that can be incorporated into more comprehensive risk management strategies. We have discussed in this article the different ways that blockchain can be used as an open network for the sharing of information and the authorization of it, which opens up multiple possibilities for building reliable artificial intelligence models for e-Health. A variety of proposed algorithms, as well as decision-making capability, as well as large quantities of data will be used by AI in order to help healthcare professionals access the medical records of patients on the blockchain. T¬¬his will lead to a generalized improvement in the efficiency of the medical system, a reduction in costs, and a level of democratization in the healthcare delivery system with the inclusion of the latest advances of these technologies. Cryptographic records are stored on blockchains, which are required by AI to store cryptographic information. Thus, the main aim of this article is to develop the secure e-health framework using artificial intelligence and blockchain technology called (SEHFUAIBC). The design science methodology (DSM) is used in this study. The developed SEHFUAIBC consists of seven components: advanced encryption algorithms, access control, multi-factor authentication, AI-based threat detection, blockchain-based data sharing, privacy protection, and audit trail. The developed SEHFUAIBC evaluated using real scenario. Based on the results of this study, it is evident that a combination of AI and blockchain in the framework produced by this study results in hybrid security techniques which hold the keys to protecting e-health records against unauthorized access.

Keywords: blockchain technology, artificial intelligence, e-Health, design science research.

I. INTRODUCTION

Assert that health informatics techniques are typically based on a sequence of conditional steps that can be visualized as a series of repeated patient-care activities in the context of budgeting, personnel, patients, legal disputes, logistics, supplies, and other procedures and medical workflows (Alotaibi and Federico, 2017). According to (Chapuis et al., 2010), hospitals and others that provide healthcare should increase the level of internal controls, improve the level of performance, compliance, and consistency, and reduce the level of risk, job time, and overhead. Based on advanced healthcare blockchain research and a robust approach to healthcare management, this article outlines an advanced healthcare blockchain analysis and a robust approach to healthcare management in order to simplify complicated medical treatments (Campanella et al., 2016). A blockchain based solution to healthcare management has been presented based on cutting-edge blockchain research in healthcare and we have analysed cutting-edge blockchain studies in healthcare. Governments and related sectors are becoming more involved in digitizing healthcare systems around the world, as demonstrated by numerous initiatives conducted in various countries and economies. The critical challenge to success is to integrate technology into the DNA of each company in a manner that utilizes blockchain, artificial intelligence, and other technologies to accomplish this (Wong, Zhou and Zhang, 2019; Bragazzi et al., 2020). According to (Sahoo and Baruah, 2018), in order to advance the field of medical research and achieve patient-centricity, technology will be utilized to facilitate user- and customer-centric

interfaces and generate data-driven decisions to generate innovative data processing approaches and better results for improving the welfare of patients. By using artificial intelligence (AI), for instance, it is possible to identify and prioritize individual patients to monitor and grow their drug production. This is extremely important to manage drug production and shorten production timelines (Mak, Wong and Pichika, 2023). The authors in (Agu and Obulose, 2024) used numerical drug design methods and artificial intelligence to monitor clinical trial data in order to repurpose marketed medications, investigate the effectiveness of medication formulations, and measure dosage using data collected in clinical. Due to the rapidly changing climate in which we are currently living, it is increasingly critical that governments identify the most effective methods by which they can leverage resources to drive reforms while ensuring the required consistency, compliance, or data protection (Siyal et al., 2019). Blockchain is an innovative solution that makes it possible to develop and manage content blocks with safe and automated data analysis in an environment where it is constantly evolving. In order to provide timely updates to medical experts, healthcare providers, and payers regarding the status of health-related data, all health-related data will be securely recorded and analysed.

Moreover, Artificial Intelligence can also execute complex computations and be capable of rapidly analysing vast quantities of patient data in order to help make medical decisions (Priyanka et al., 2024). The use of AI in healthcare, however, remains unpopular with some doctors, particularly when it comes to positions that could have a significant impact on a patient's wellbeing. I don't think there can be any argument in Favor of the use of artificial intelligence, as it has proven to be capable of executing many profound and sophisticated tasks more rapidly than a person. There is no doubt that the automotive industry can exploit artificial intelligence to deliver driverless vehicles in the near future. By utilizing machine learning, other companies are already able to detect fraud or determine financial threats, allowing them to identify threats at an early stage. In terms of AI maturity level, only a few points could be considered to be indicators (Akkiraju et al., 2020).

Thus, the aim of the study is to design a framework for a secure e-health system using artificial intelligence and blockchain technologies, which will be called SEHFUAIBC. For the purpose of this study, we are using the design science methodology (DSM). As a result of SEHFUAIBC's development, seven underlying components have been developed: advanced encryption algorithms, access control, multifactor authentication, AI-based threat detection, data sharing based on blockchain, privacy protection, and audit trail checks. A real-life scenario was used to evaluate the developed SEHFUAIBC.

The rest of this article is arranged as follows: the related works is discussed in Section 2, and the methodology is presented in Section 3. The problems statement and objectives are discussed in Sections 4 and 5 respectively. The results and discussion and limitations are introduced in Sections 6 and 7 separately, where the conclusion and future works are offered in Section 8.

II. Related Works

There are some research articles and projects proposed in the literature which focused on E-Health sector from the security perspective using Artificial Intelligence and Blockchain Technology. For example, the authors of (Tagde et al., 2021) emphasized the importance of integrating generalizable analytics into a comprehensive risk management strategy, as well as how they promote a significant impact on healthcare. They demonstrated how blockchain, an open network for sharing information and authorizing it, can be used to create reliable artificial intelligence models in e-Health.

The authors in (Alabdulatif et al., 2023) proposed an enhanced and more secure way of protecting the learning model's decision-making process by extending the scope and security. In this study, smart contracts were used to implement the decision function of the learning model using the extracted learning parameters by reverse engineering the decision function of the learning model.

The researchers of (Kubendiran, Singh and Sangaiah, 2019) provided a framework for implementing blockchain in e-health care systems to verify data integrity efficiently. Furthermore, they presented an innovative concept for ensuring data provenance, which is a crucial aspect of healthcare that needs to be addressed.

Using blockchain's unique properties, the authors of (Sanjana et al., 2021) proposed a framework for implementing confidentiality, authentication, and data sharing which are all important aspects to consider when handling sensitive information, and the use of the framework has been endorsed by peers. As part of the framework for a secure e-health system, blockchain is utilized as a method of capturing electronic health records (EHR), securely storing them, and integrating IoT and fog computing infrastructure to provide secure storage and analytics.

The authors on (Quasim et al., 2020) developed a secure system using blockchain technology to ensure the protection of electronic health records (EHRs). Several components have been integrated into the framework, such as sensors, Internet of things, databases, and other computer resources. There is a framework for securing electronic health records that will improve the security and privacy of electronic health records as compared to traditional healthcare systems.

The authors in (Velliyangiri et al., 2022) developed a new approach that applies the blockchain technology to health records and provides a decentralized view, improves medical accuracy, mitigates risk factors, and prevents health problems before they occur.

A blockchain-based electronic health record (BEHR) transmission between physicians and patients was introduced by (Basetty, 2021) as an integrated approach to blockchain 4.0 technology. This reduced latency in health care records transmission using IoT-based cloud environment.

A Blockchain-based solution was proposed by (Jennath, Anoop and Asharaf, 2020) to address the security and privacy concerns that have otherwise not been addressed by current eHealth systems, in order to address the security and privacy concerns that currently exist. Furthermore, this study explores the possibilities of building trusted AI models over blockchain for implementation in the area of e-Health, where a platform for the sharing of consent-based data is designed to allow for transparent data collection.

A system for ensuring authentication and also protecting medical records' integrity was developed by (Nagasubramanian et al., 2020), utilizing the cloud. Through the implementation of the proposed system, a keyless signature infrastructure will ensure the secrecy of digital signatures and authentication for digital signatures. Also, the proposed blockchain technology has the capability of maintaining data integrity.

A secure data dissemination scheme for IoT-based e-health systems based on IoT is proposed by (Kumar et al., 2022) in the form of an artificial intelligence-based blockchain framework. An approach based on deep learning was used to detect intrusions at the edge of the network using an intrusion detection system that uses deep learning to detect intrusions.

By utilizing deep learning and cryptography technologies, the authors in (Veeramakali et al., 2021) have created an intelligent IoT and healthcare diagnosis model that combines deep learning with cryptography to provide secure and reliable diagnostics using deep learning. A proposed model consists of three main processes: secure transactions, hash-value encryption, and the diagnosis of medical conditions.

A cryptographic framework based on blockchain technology is proposed by (Ghazal et al., 2022) in order to provide security-based solutions that are based on a computational intelligence approach. The proposed approach is able to provide better results in terms of 0.93 in the training phase and 0.91 in the validation phase when it comes to training.

The framework proposed by the (Chakraborty, Aich and Kim, 2019) sets an excellent example for the complete supervision of a cure or a continuous treatment or generic healthcare from the onset right up to the very end of the treatment course. In the case of healthcare data research, trust and authenticity of the data are two of the primary notions that are always observed in the case of analysing the data.

A novel blockchain approach has been developed by (Samad, 2022) for the purpose of evaluating different methods of sharing decentralized views of health information and improving medical accuracy, health, and prevention of health disorders through the use of blockchain technology in the field of eHealth. The goal of the work was to discover the benefits of blockchain technology for improving health.

The authors in (Verma, 2024) present a novel blockchain technology that enables the secure storage of health data in the cloud. As a result, medical records can be authenticated in a secure environment and maintain their integrity. An improved blowfish model that guarantees the authentication of the blockchain is deployed here as a method of deploying blockchains with optimal encryption.

The authors of (Jakhar et al., 2024) proposed a privacy-preserving access control framework that utilizes blockchain technology to ensure that healthcare data integrity, security, accessibility, and privacy are maintained while using consensus-driven decentralized data management through peer-to-peer distributed computing platforms.

In reviewing the existing models and frameworks developed for securing the e-Health industry, we found these challenges and issues that need to be addressed which are shown in Figure 1. Therefore, this study aims to develop a secure

framework that can cope with these issues. This is done by combining modern blockchain technology with artificial intelligence.

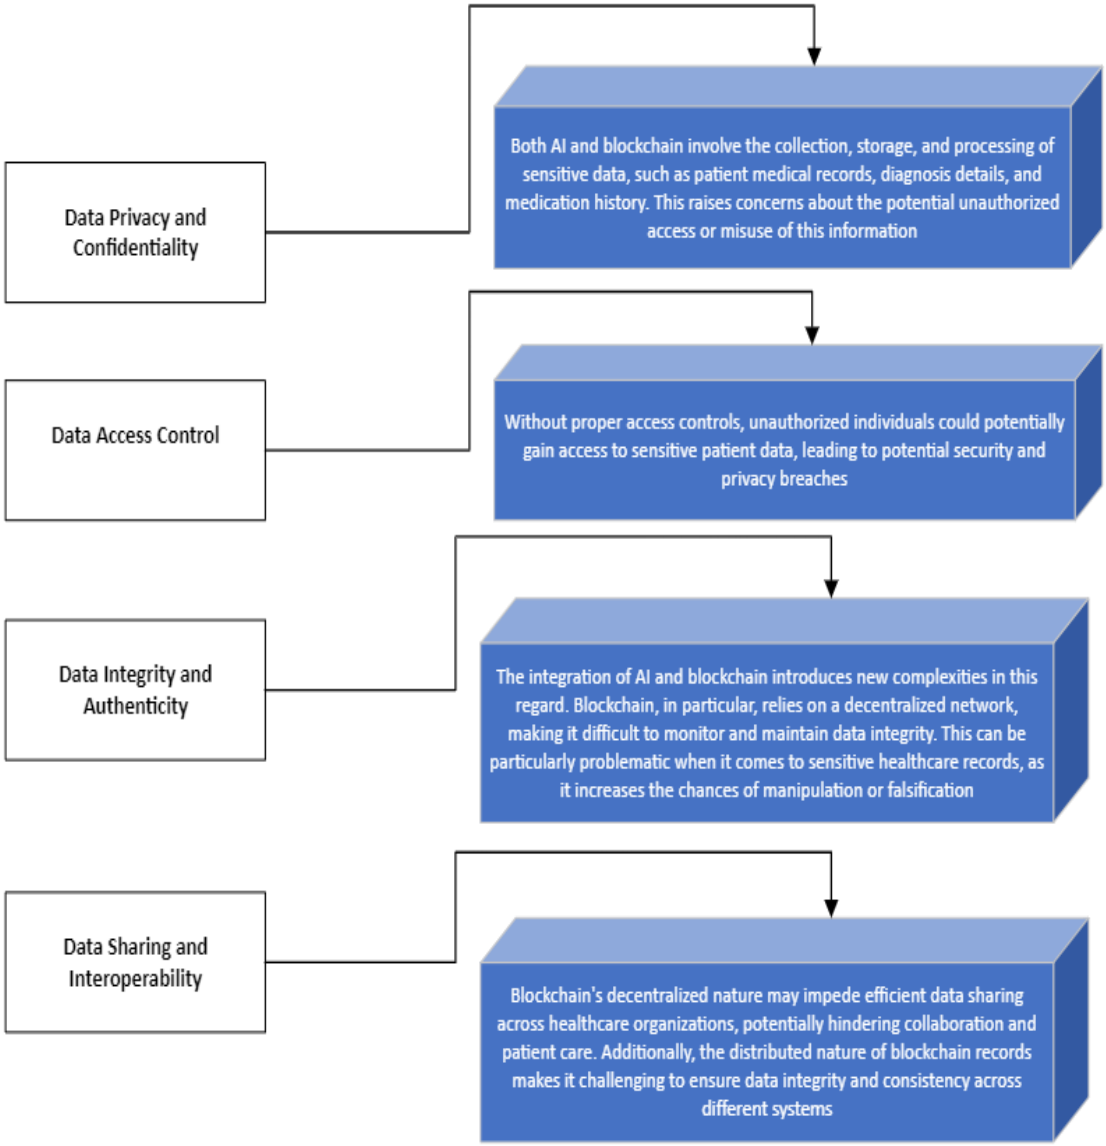

Fig. 1: Discovered challenges and issues for securing the e-Health industry.

III. Problem Statement

AI and blockchain are used to collect, store, and process sensitive data, including medical records, diagnosis details, and medication history. Consequently, this information is at risk of being accessed or misused by unauthorized parties. A lack of appropriate access controls could lead to potential security and privacy breaches involving sensitive patient data.

IV. Objectives of the Study

The main aim of this study is to develop the secure e-health framework using artificial intelligence and blockchain technology called (SEHFUAIBC).

V. Methodology

The DSM is applied in this study (March and Smith, 1995). It is a qualitative research approach that combines a design process to learn how an artifact is designed and how the design is constructed, which is what is known as design science research (March and Smith, 1995; Alotaibi, Al-Dhaqm and Al-Otaibi, 2023; Alotaibe, 2024; Alotibi, 2024). It uses this process to learn how both the design itself and how it is constructed work together. The goal of DSR is to optimize the

performance of (designed) artifacts by developing new methods and techniques that will promote the development of them as well as their performance (Al-Dhaqm et al., 2020). The adapted methodology consists of three stages as shown in Figure 2.

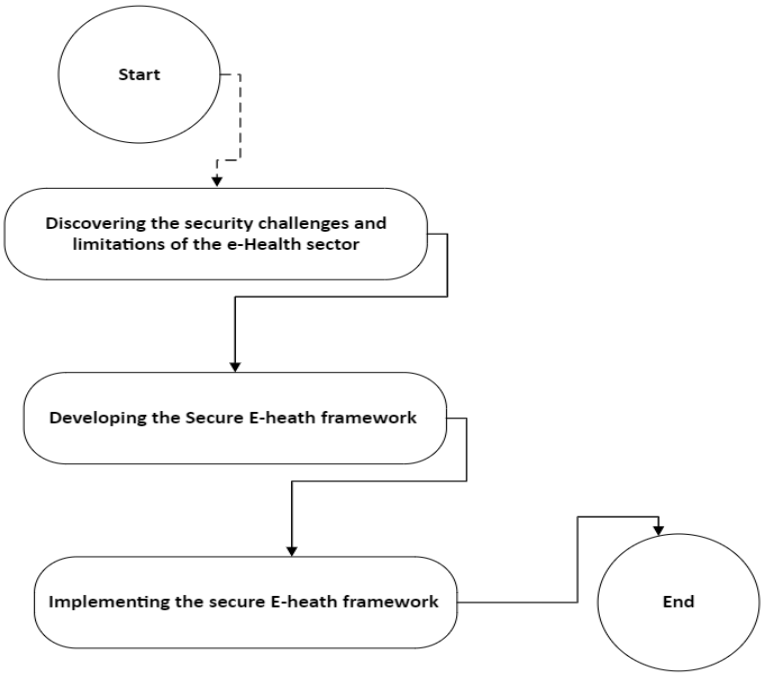

Fig. 2: Adapted methodology (March and Smith, 1995)

Stage 1: Discovering the security challenges and limitations of the e-Health sector: The purpose of this step is to examine security challenges and limitations in the e-Health sector. Security challenges in the e-Health sector have been addressed by several models, frameworks, and approaches. Nevertheless, these models and approaches are specific and developed for different scenarios, according to the literature. Table 1 displays the challenges and contributions of the existing works for the e-Health sector.

Table 1. The challenges and contributions of the existing works

Ref	Security Techniques	Challenges	Contributions
(Tagde *et al.*, 2021)	Blockchain technology and AI	Discussed the issues of sharing information and authorizing it, as well as how AI and blockchain can be used in the eHealth field to create reliable models of clinical diagnosis and treatment.	Integrated generalizable analytics into a comprehensive risk management strategy would have a significant impact on healthcare.
(Alabdulatif *et al.*, 2023)	Blockchain technology: Smart contracts	They discussed the challenges and issues that are involved in the implementation of the E-Health framework for safer decision making.	Incorporate blockchain and machine learning into an AI framework based on trust. Create immutable smart contracts that provide effective security for Support Vector Machine (SVMs) and Multi-Layer Perceptron (MLPs).
(Kubendiran, Singh and Sangaiah, 2019)	Blockchain technology	They discussed the challenges of maintaining data integrity efficiently in e-health records.	Establishing an efficient framework for implementing blockchain in e-health care systems. Provided an innovative approach to ensuring the provenance of health data.
(Sanjana *et al.*, 2021)	Blockchain technology	A number of important issues, such as confidentiality, authentication, and data sharing, were discussed by the authors.	Blockchain is used to capture electronic health records (EHR), store them securely, and integrate IoT and fog computing to provide secure storage and analytics

(Quasim *et al.*, 2020)	Blockchain technology	Examined ways of improving electronic health records' security and privacy compared to traditional healthcare systems by securing them.	The use of blockchain technology as a secure way to ensure the protection of electronic health records (EHRs) has been developed.
(Velliyangiri *et al.*, 2022)	Blockchain technology	They discussed medical accuracy, reduction of risk factors, and preventing health challenges before they arise, as well as the importance of medical accuracy.	Using blockchain technology, they developed a decentralized view of health records. Preventing health problems before they occur, mitigating risk factors, and improving medical accuracy are all advantages of this.
(Basetty, 2021)	Blockchain technology	Using an IoT-based cloud environment, they discussed the limitations of reduced latency in the transmission of health care records.	Provided a blockchain-based system to facilitate the transmission of health records between doctors and patients.
(Jennath, Anoop and Asharaf, 2020)	Blockchain technology and AI	Current eHealth systems do not address security concerns or privacy concerns adequately.	Using Blockchain for trusted AI models in the area of e-Health, involves sharing consent-based data for transparent data collection. The use of Blockchain technology in eHealth has been proposed to resolve security and privacy issues that have otherwise not been addressed.
(Nagasubramanian *et al.*, 2020)	Blockchain technology	Discussed the issues of certifying medical records and ensuring the integrity of the records.	Provided secrecy and authentication for digital signatures by implementing a keyless signature infrastructure. Maintaining data integrity, blockchain technology is capable of securing transactions.
(Kumar *et al.*, 2022)	Blockchain technology and AI	To detect intrusions at the edge of the network, they discussed using deep learning-based intrusion detection systems.	Proposed an artificial intelligence-based blockchain infrastructure for securely disseminating data for IoT-enabled e-health systems based on IoT.
(Veeramakali *et al.*, 2021)	AI	They discussed the security and reliability issues associated with the use of deep learning to diagnose medical records were discussed.	Provided secure and reliable diagnostics using deep learning and cryptography in IoT and healthcare.
(Ghazal *et al.*, 2022)	AI	The limitations relating to the sharing of medical records and the sharing of data were discussed.	A cryptographic framework based on blockchain technology is proposed. Provided security-related solutions using a computational intelligence approach, a cryptographic framework based on blockchain technology.
(Chakraborty, Aich and Kim, 2019)	Blockchain technology	They highlighted the limitation of trust and authenticity of the data in healthcare data research as two of the fundamental aspects of data analysis.	Presented an excellent model for supervising a cure from the beginning to the end of the treatment. Providing complete supervision of a cure, continuous treatment, or generic healthcare.
(Samad, 2022)	Blockchain technology and AI	Examining the challenges of sharing decentralized views of health information and improving health, medical accuracy, and prevention of disease through blockchain technology in eHealth.	Developed a blockchain approach to examine different methods of sharing centralized views of health information. Improved medical accuracy, health, and prevents health disorders.
(Verma, 2024)	Blockchain technology	The challenge of authenticating medical records in a secure environment and maintaining integrity of medical records were discussed.	Presented a new blockchain technology that enables the secure storage of health records in the cloud by using a distributed ledger technology.

			Presented a method of deploying blockchains with optimal encryption based on improved blowfish models.
(Jakhar *et al.*, 2024)	Blockchain technology	They discussed challenges in maintaining integrity, security, accessibility, and privacy in healthcare data through consensus-driven decentralized management through peer-to-peer distributed computing platforms.	Propose a privacy-preserving access control framework based on blockchain technology. To ensure decentralized management of healthcare data, peer-to-peer distributed computing platforms are used to ensure integrity, security, accessibility, and privacy of healthcare data.

Stage 2: Developing the Secure E-heath framework: The goal of this stage is to develop a secure e-health framework that utilizes the power of artificial intelligence (AI) and blockchain technologies to provide a quality healthcare experience. We developed the framework to provide a robust and secure platform for handling sensitive healthcare information that can manage a wide range of risks. In addition to protecting patient privacy, the secure e-health framework ensures interoperability and accessibility of data. The framework will address data breaches, unauthorized access, and limitations in interoperability caused by traditional healthcare data management systems. The secure e-health framework consists of several key components that work together to ensure the secure management of patient data as shown in Figure 3. These components include:

- *Data Encryption*: Encrypting all health data using advanced encryption algorithms is an essential step to protect patient confidentiality and prevent unauthorized access. By implementing robust encryption measures, healthcare organizations can safeguard sensitive medical information, comply with regulatory requirements, and ensure the safety of patient data. Therefore, it is crucial for healthcare organizations to prioritize data encryption as part of their overall security strategy.
- *Access Control*: Robust access control mechanisms are essential in protecting the health data of individuals and organizations. By implementing access control, organizations can ensure that only authorized individuals or entities have access to sensitive data, protecting privacy, confidentiality, and the integrity of the data.
- *Multi-Factor Authentication*: Multi-factor authentication, including biometric authentication, has become an essential component of robust security strategies. By combining multiple factors and utilizing unique physiological or behavioral characteristics, organizations can significantly enhance the security of their systems and protect against unauthorized access. Embracing biometric authentication not only improves security but also offers a more convenient and efficient authentication experience for users. Organizations should consider implementing biometric authentication as part of their overall security framework to safeguard sensitive data and maintain the trust of their customers.
- *AI-Based Threat Detection*: AI algorithms can be employed to detect anomalies in health data, such as unauthorized access attempts or suspicious activities, triggering alarm bells. AI-based threat detection offers a valuable solution for enhancing the security of health data. By employing AI algorithms to detect anomalies and trigger alarm bells, healthcare organizations can proactively protect patient data from unauthorized access attempts and malicious activities. With the ongoing evolution of cyber threats, it is crucial for healthcare institutions to invest in AI-powered security solutions to stay one step ahead and ensure the safety and privacy of their patients' data.
- *Blockchain-based Data Sharing*: Health data can be stored and shared on a blockchain platform, ensuring secure transmission and immutability. Blockchain-based data sharing has the potential to revolutionize the healthcare industry by improving data security, promoting collaboration, and enhancing patient care. By leveraging the immutability and decentralized nature of blockchain technology, health data can be securely shared among authorized parties, leading to improved patient outcomes, research advancements, and the overall efficiency and quality of the healthcare system. As blockchain technology continues to evolve, it is important to address the challenges associated with its implementation and explore potential solutions that maximize the benefits it offers.
- *Privacy Protection:* Privacy-enhancing techniques, such as data anonymization or tokenization, can be employed to preserve patient privacy while sharing data securely. privacy-enhancing techniques, such as data anonymization and tokenization, can be employed to preserve patient privacy while sharing data securely. By implementing secure data sharing practices and employing these privacy-enhancing techniques, healthcare organizations can ensure that patient data is protected while maintaining the ability to share crucial information with authorized parties.
- *Audit Trail*: A blockchain audit trail allows users to track the origin and evolution of health data, ensuring transparency and accountability. Blockchain audit trails offer a secure, transparent, and accountable approach to tracking the origin and evolution

of health data. By leveraging the unique features of blockchain technology, healthcare organizations can ensure the security and integrity of health data, ultimately improving the quality of care provided to patients.

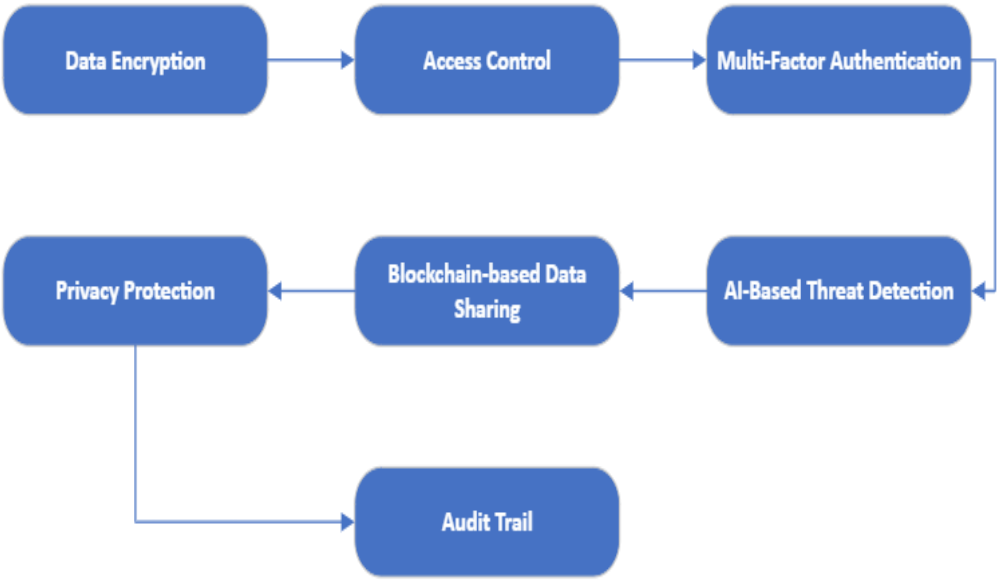

Fig. 3: Secure E-Health Framework Using Artificial Intelligence and Blockchain Technology (SEHFUAIBC)

Stage 3: Implementing the secure E-heath framework: To implement the developed SEHFUAIBC we used the following scenario: This scenario explains how the developed SEHFUAIBC can secure the medical records of the patients. John is a 45-year-old patient who has just visited his local healthcare provider for a routine checkup. During the checkup, John's doctor accessed his medical history, including his diagnosis and treatment plans, in order to make informed decisions about his overall health. This data, known as health, records, contains sensitive information that is crucial for John's care and may need to be shared with various healthcare professionals and organizations. Unfortunately, during the appointment, John noticed that his medical record was not being protected adequately. Concerned about his confidentiality, he asked his doctor about the security measures in place to safeguard his data. The doctor assured John that all necessary precautions had been taken, but upon further examination, John realized that his concerns were valid.

To address these issues and protect confidentiality, integrity, privacy, and availability of the medical history of the patient the developed SEHFUAIBC is applied as shown in Figure 4. Using advanced algorithms for encryption, access control, multifactor authentication, artificial intelligence-based threat detection, blockchain-based data sharing, privacy protection, and the use of audit trails, we can safeguard sensitive medical information and prevent it from being compromised. Modern encryption algorithms, such as RSA and AES, employ complex mathematical algorithms to encrypt data, making it unreadable without the necessary decryption keys. These algorithms ensure that even if unauthorized individuals gain access to encrypted health records, they will not be able to decipher or misuse the information. By encrypting all health data, healthcare organizations can safeguard patient information and ensure their safety. By protecting patient data from unauthorized access, healthcare organizations can prevent data breaches, identity theft, and privacy violations. This not only protects the patients' well-being but also helps maintain the integrity of the healthcare system.

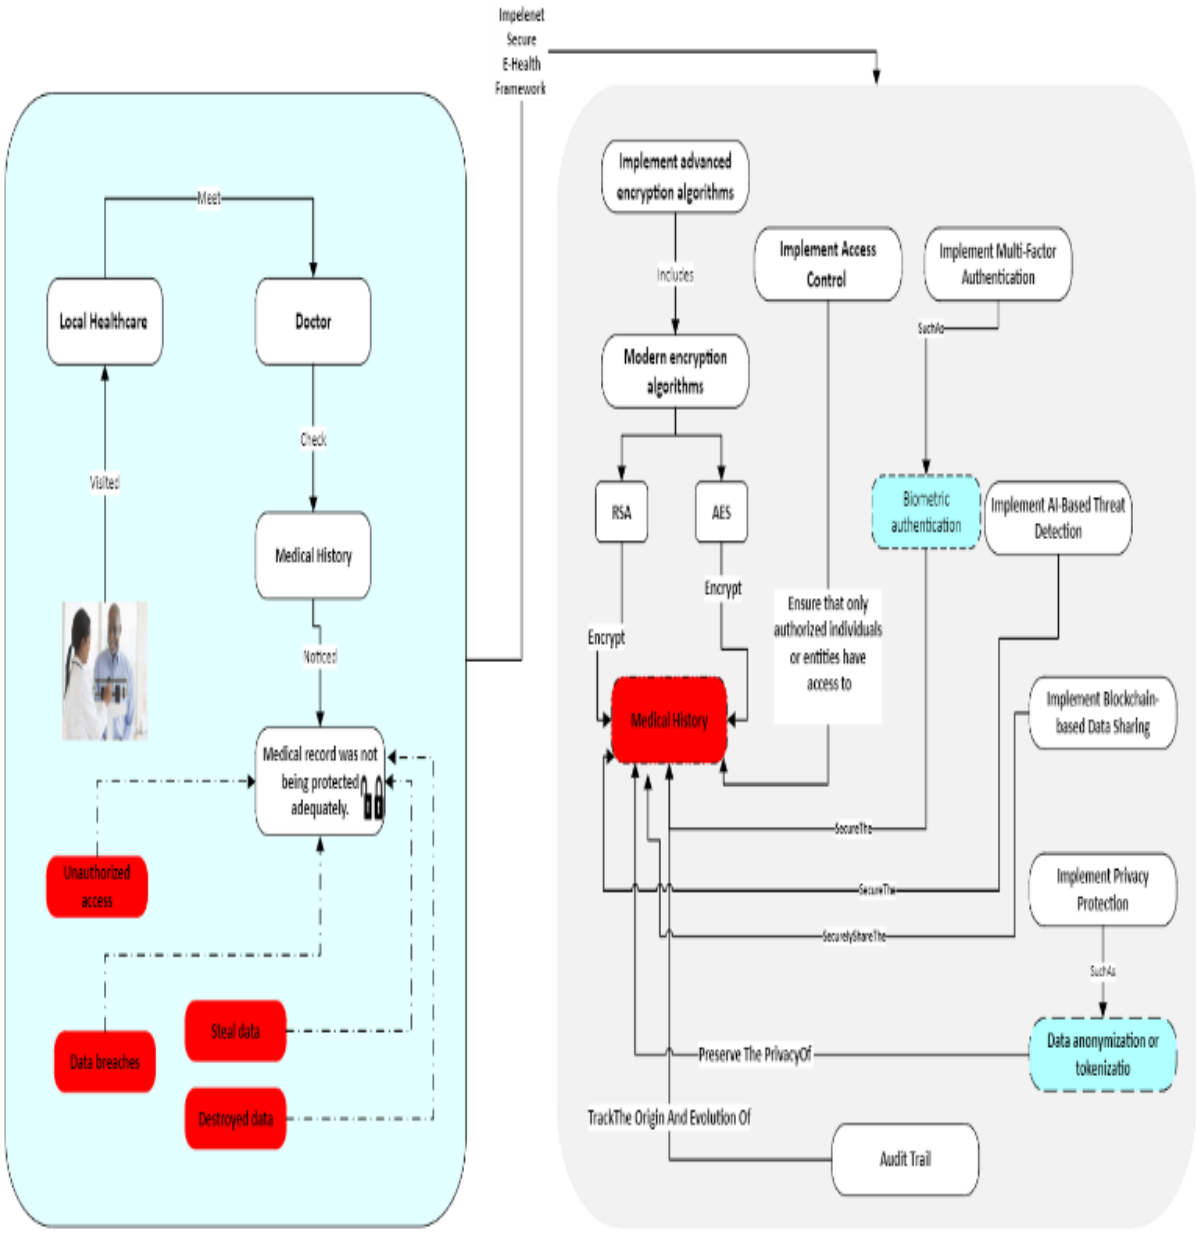

Fig. 4: Real scenario of implementing the secure e-health framework for protecting the medical history of patients

VI. RESULTS AND DISCUSSIONS

The purpose of this study was to highlight the security challenges that are associated with the e-health sector, as well as the contributions which were provided by existing studies in this area. Based on research on the security challenges and issues of the e-Health sector, SEHFUAIBC is developed based on blockchain and AI mechanisms.

The existing works focused on the four main security challenges of the e-Heath records which are: authorization, sharing data, integrity, and privacy. One of the key challenges in e-Heath sector is ensuring appropriate access controls to medical records. For example, a healthcare provider responsible for treating a patient should be able to access only specific information related to that patient, while an administrator responsible for system maintenance should have limited access to patient data. The second challenge is the sharing medical data among healthcare providers is essential for efficient collaboration and continuity of care. However, sharing medical data securely can be a challenge due to concerns about confidentiality and the potential for unauthorized access. For example, a hospital can share a patient's medical records with another healthcare facility through a secure messaging system, ensuring that only the intended recipient can view the data. The third challenge is the integrity of medical data. Thus, healthcare organizations need to ensure that electronic medical data is accurate, complete, and unaltered. To address this challenge, healthcare organizations can implement robust data

integrity measures. This can include the use of digital signatures to verify the authenticity of medical data, as well as regular data backups and disaster recovery plans. Healthcare organizations should also establish policies and procedures for data validation and verification, ensuring that any changes made to medical records are properly recorded and justified. For example, a hospital can implement a system that automatically checks and verifies the integrity of medical data, such as patient demographic information or medication records, to prevent unauthorized changes. The last challenge is the privacy of medical data. Healthcare organizations need to implement robust security measures to protect patients' personal information from unauthorized access or use. This includes implementing a comprehensive data privacy and security framework, including policies, procedures, and technologies to protect patient information from unauthorized access, disclosure, or alteration. Healthcare organizations should also educate their staff about the importance of privacy and ensure their compliance with privacy guidelines. For example, a hospital can store patient information in secure data centers, protected by physical and technical security measures, to prevent unauthorized access. Additionally, the hospital can implement strict access controls, such as role-based access controls, to limit who can access and view patient data.

In order to address the challenges mentioned above, the SEHFUAIBC was developed in the present study. It utilizes a combination of blockchain technology and artificial intelligence technologies to make sure that e-health records are confidential, secure, private, and accessible. A real-world scenario is used to test the applicability of the developed SEHFUAIBC. The implementation of SEHFUAIBC has proven that the framework that has been developed is robust and can secure medical records and protect them from unauthorized users, data theft, and unauthorized destruction by providing a robust framework.

VII. Limitations and Open Directions

As a result of the use of artificial intelligence and blockchain technology, sensitive data such as patient medical records, diagnosis details, and medication history are collected, stored, and processed. There is a danger that this information could be accessed by unauthorized individuals or misused. There is a potential for significant security and privacy breaches if there are no proper access controls in place to prevent unauthorized individuals from gaining access to sensitive patient data. AI and blockchain are now being integrated into this aspect of the project, which introduces a number of new challenges. Since a blockchain is based on a decentralized network of nodes, it is very difficult to monitor and maintain the integrity of the data since it relies on a decentralized network. There is a particular problem when it comes to sensitive healthcare records, since it is a high likelihood that they could be manipulated or falsified as a result. The dispersed nature of blockchain technology may make it difficult for healthcare organizations to share data efficiently across organizations. This could harm patient care and collaboration. Moreover, because blockchain records are distributed, it can be challenging for the data integrity and consistency to be maintained across multiple systems due to the distributed nature of blockchain records.

VIII. Conclusions

Blockchain and AI are emerging technologies in healthcare. In order to collect information on healthcare indices, documents published on Web of Sciences and other Google surveys conducted by a range of governing bodies are used to collect the information. The purpose of this review is to examine a wide range of aspects of blockchain and artificial intelligence, along with how these two technologies can be integrated to make a significant contribution to healthcare. In addition, it is recommended to implement generalizable analytical technologies that can be incorporated into a more comprehensive risk management strategy in order to make a significant contribution to healthcare. This article discusses the various ways that blockchain technology can be used as an open network for sharing information as well as allowing it to be authorized, which opens up a number of opportunities for building reliable artificial intelligence models for e-Health applications. The AI will be able to access the medical records of patients on the blockchain by using a variety of algorithms and decision-making capabilities, as well as a large amount of data, in order to assist healthcare professionals in accessing the medical records of patients on the blockchain. This will lead to a generalized improvement in the efficiency of the medical system, a reduction in costs, as well as a degree of democratization in the healthcare delivery system, since it will incorporate the latest advancements in these technologies, resulting in an improvement of efficiency in everything related to healthcare. There are blockchains which are used to store cryptographic records, which is a requirement for AI to store cryptographic records. Hence, the objective of this article is to propose a secure e-health framework using artificial intelligence and blockchain technology that is referred to as SEHFUAIBC. In this study, the design science methodology (DSM) is used to conduct the research. As a result of the development of the SEHFUAIBC, the system consists of seven elements: advanced encryption algorithms, access control, multi-factor authentication, AI-powered threat detection,

blockchain-based data sharing, privacy protection, and audit trail. A real-world scenario was used to evaluate the SEHFUAIBC developed. Based on the results of this study, it is evident that a combination of AI and blockchain in the framework produced by this study results in hybrid security techniques which hold the keys to protecting e-health records against unauthorized access.
